

Acquisition of quantity, relevance and word learning inferences, and their relationship with Theory of Mind

Elsbeth Wilson & Napoleon Katsos, Department of Theoretical and Applied Linguistics, University of Cambridge

Aims

1. What is the relationship between scalar quantity, ad hoc quantity and relevance implicature inferences in children's pragmatic development?
2. Is word learning by exclusion a similar pragmatic inference?
3. What is the relationship between pragmatic inferencing and Theory of Mind development?

Background

- Recent studies find younger age of development for implicature inferences, down to 3 years, but studies focus on single implicature type [1] [2]
- Word learning by exclusion has been proposed as a pragmatic forerunner to implicatures [3], or as a lexical heuristic [4], but no comparison with undisputed pragmatic skills has been made to test this
- A Gricean model of implicatures implies reasoning about others' beliefs and intentions – Theory of Mind – and increasing complexity of inferences from word learning, to relevance, ad hoc quantity, then scalar implicature [5]

Method

- Inference type (Scalar, Ad hoc, Relevance, Word Learning) x Critical/Control x Agegroup
- 32 items across 5 'stories', binary picture-selection task, narrated by experimenter and puppet (recorded)
- Theory of Mind tests: Sally-Anne and unexpected contents tasks [6] [7]
- N = 71 monolingual English-speaking children aged 2;8 - 5;11. N = 15 adult controls

Results

- Adults score at ceiling in all conditions
- For children, a mixed effects logistic regression model, with Inference Type, Critical/Control and Agegroup as fixed effects (sum coding), and Item by Condition, Agegroup and story order random slopes, shows a main effect of condition (control higher than grand mean), inference type (scalar lower), and Agegroup (2;8 - 3;11 lower) – Table 1.
- The same model but with successive difference contrasts indicates: Relevance is lower than Word Learning; no difference between Relevance and Ad Hocs; but Scalars lower than Ad Hocs. Also, 4-yos perform worse overall than 5-yos, and 3-yos worse than 4-yos – Table 2.
- For agegroup 2;8-3;11, there is no evidence for a relationship between Relevance and Word Learning inferences ($\tau = -.05$, $z = -.34$, $p = .73$), but between Ad Hoc and Word Learning ($\tau = .34$, $z = 2.3$, $p = .02$)
- Model comparison shows that ToM is not a predictor of implicature score, when age, gender, SES and core language skills (grammar) are taken into account – Table 3.

Findings

- A developmental trend for pragmatic inferences: word learning emerges first, then relevance / ad hoc, then scalar implicatures
- This partially reflects complexity of inference implied by Gricean model of implicatures, and corroborates previous studies
- Word learning inferences correlate with ad hocs – suggestive of pragmatic nature of word learning by exclusion, or just because of the shared exclusion mechanism
- No evidence for relationship of implicatures and ToM here

Key Terms

Implicature – a speaker's intended meaning beyond the literal meaning of what is said, which can be inferred by assuming that the speaker is informative (quantity implicature) or relevant (relevance)

Word learning by exclusion – a strategy of picking a novel object as the referent of a novel label instead of an object with a known label

Theory of Mind (ToM) – the ability to reason about others' beliefs, desires and intentions

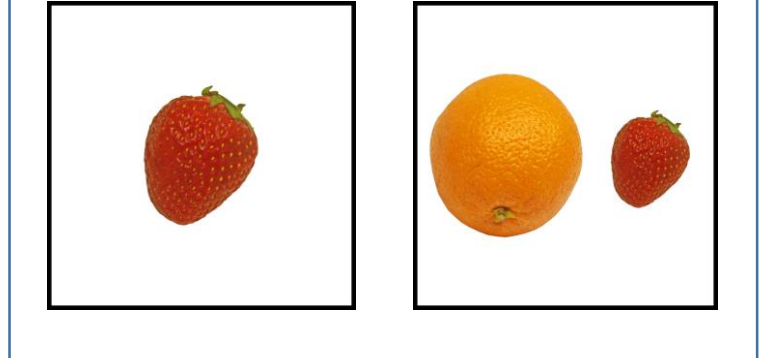

Control - semantic (Ad Hoc)	Bob came out of the kitchen. His dad asked, "What have you taken from the fridge?"	"And I said, I took an orange and a strawberry"
Relevance	It was breakfast time. Bob's dad asked, "What would you like for breakfast?"	"And I said, I'll get the milk"
Scalar quantity	Bob made a crash in the kitchen. His mum asked, "What did you do with the pile of plates?"	"And I said, I broke some of the plates"
Word learning	Bob went inside the shop and...	"I picked a dax."

Ad Hoc (Critical)

Bob came out of the kitchen. His dad asked, "What have you taken from the fridge?"

"And I said, I took a strawberry."

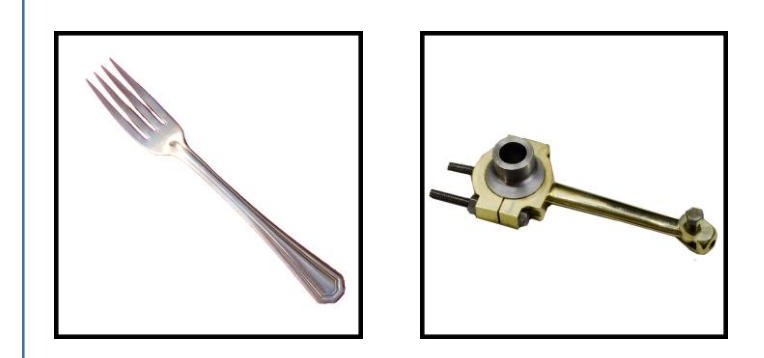

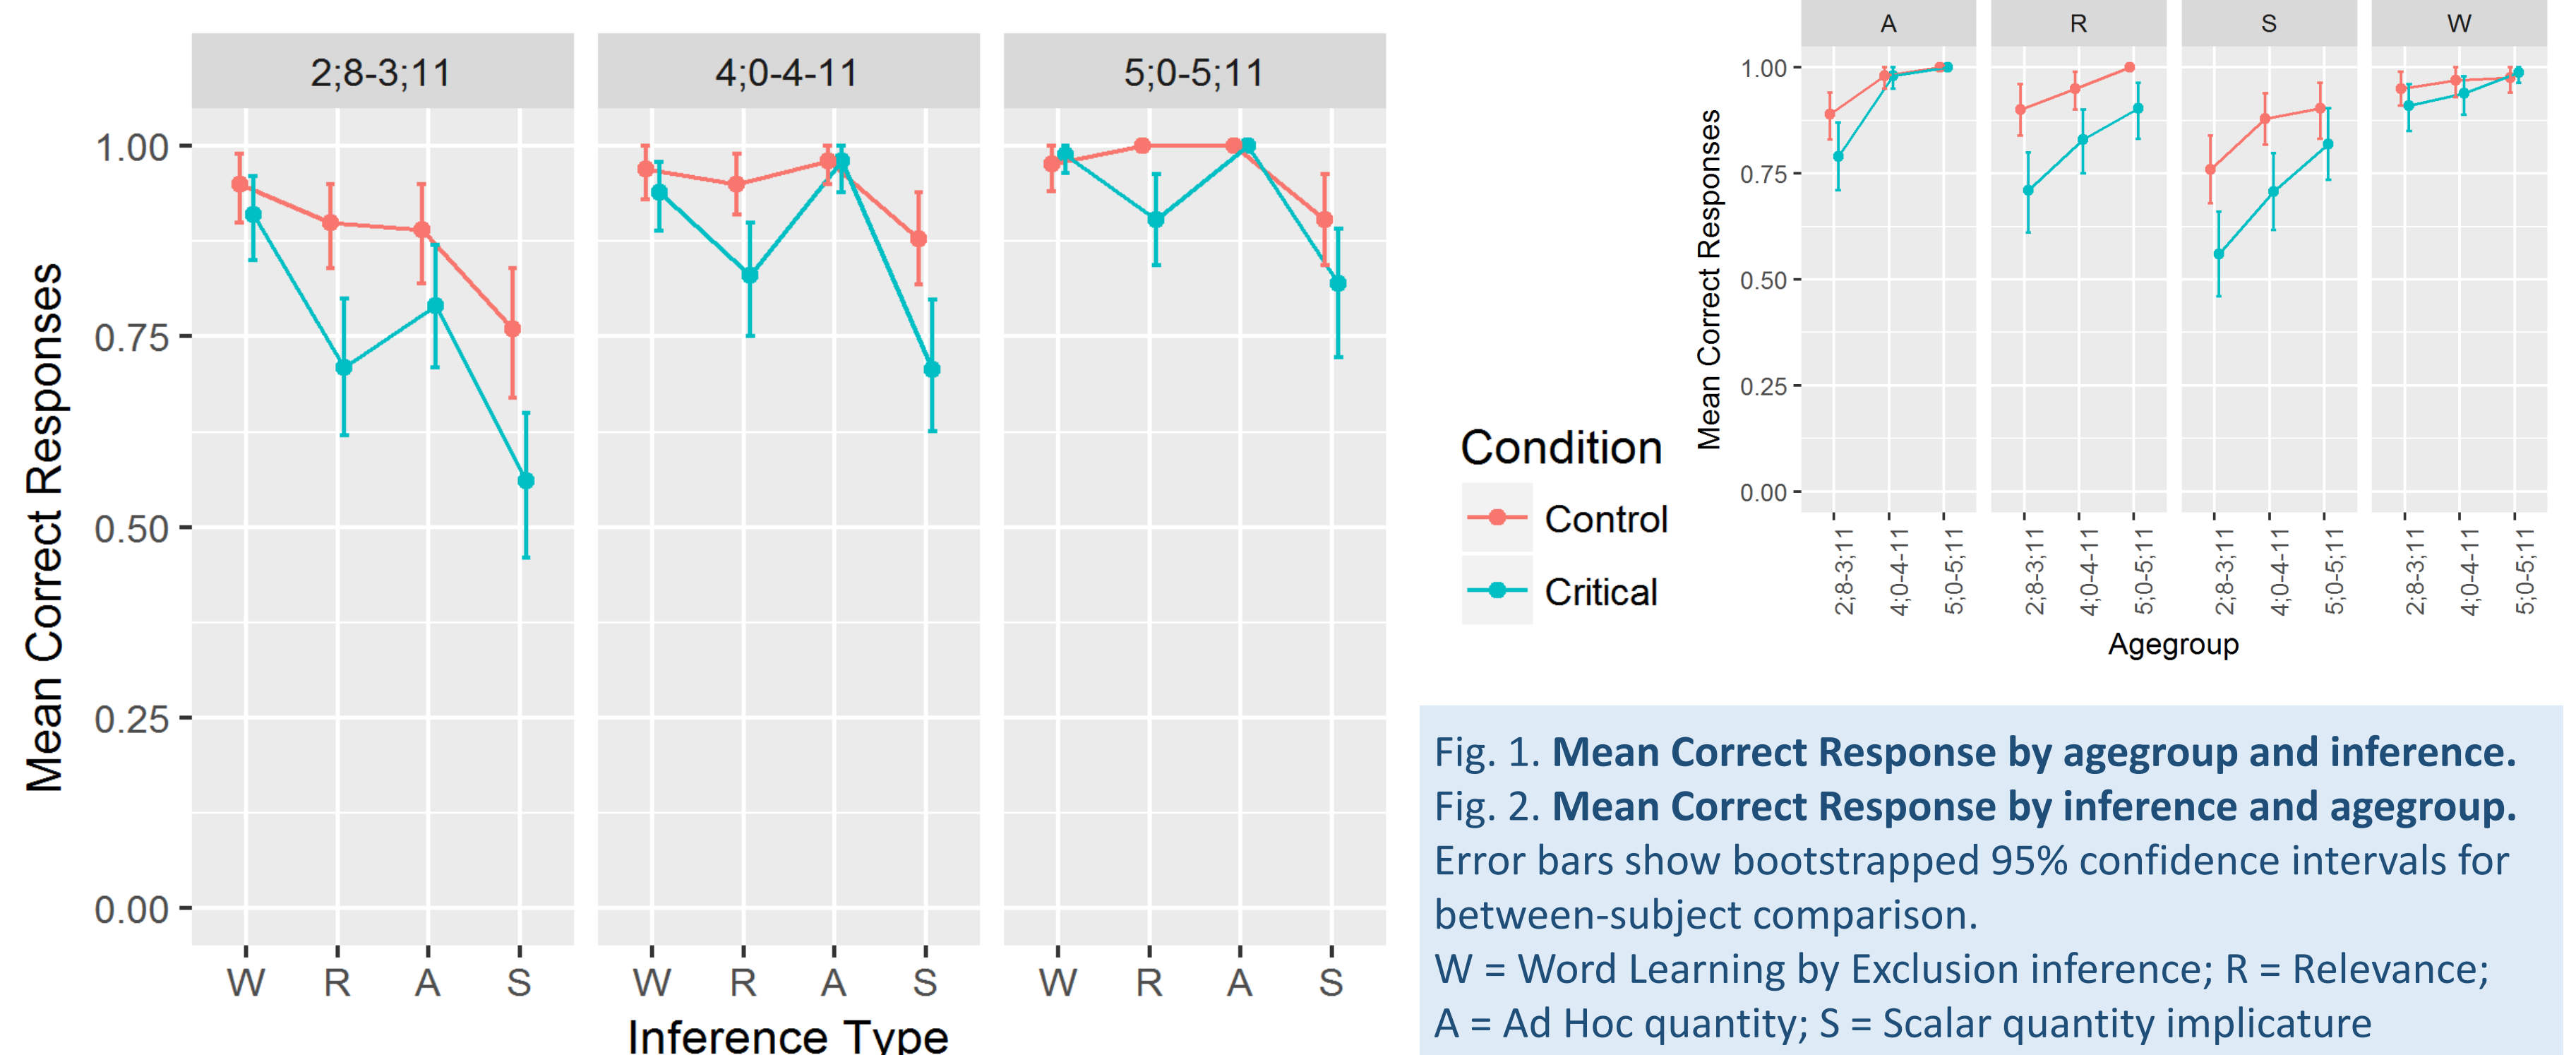

Word learning

Bob went inside the shop and...

"I picked a dax."

	Df	AIC	Log Lik	Deviance	χ^2	p
Score ~ 1 + (1 + Age + Gender + SES + Grammar + TOM + Multiling Item.no)	22	609.92	-282.96	565.92		
Score ~ Age + (ran effects)	23	582.46	-268.23	536.46	29.47	<.001
Score ~ Age + Gender + (ran effects)	24	584.35	-268.18	536.35	0.11	0.74
Score ~ Age + Gender + SES + Grammar + (ran effects)	25	582.74	-266.37	532.74	3.61	0.06
Score ~ Age + Gender + SES + Grammar + TOM + (ran effects)	26	584.16	-266.08	532.16	0.58	0.45
Score ~ Age + TOM + (ran eff)	27	586.04	-266.02	532.04	0.12	0.73

Table 3 Model comparison for Age, Gender, SES, Grammar, and ToM

Discussion

- Generally high performance due to child-friendly nature of task
- Pre-school years seem to be key stage for implicature development
- Whether word learning is pragmatic or lexical requires further research
- Contrary to Gricean model, is it possible that some pragmatic inferencing abilities do not depend on ToM [8]? Or is correlation between false-belief and implicature tasks too crude a measure? They could depend on different aspects of ToM or linguistic skills; a more integrated method is needed (see [9]).
